Stochastic wave function of a Λ system Figure 1 is a three-level Λ system. (a) Write down the effective Hamiltonian and quantum jump operators for Figure 1. (b) Suppose $|\psi_s(t=0)\rangle = |g\rangle$. Describe how the wave function evolves using pseudocode. (c) Consider a case in which there is no quantum jump in $0 < t < t_0$. Find the time evolution of the wave function and the scattering rate

$$\gamma_1 = \langle \psi_{\mathbf{s}} | C_1^{\dagger} C_1 | \psi_{\mathbf{s}} \rangle, \quad \gamma_2 = \langle \psi_{\mathbf{s}} | C_2^{\dagger} C_2 | \psi_{\mathbf{s}} \rangle. \tag{1}$$

(d) Plot the time evolution of γ_1 and γ_2 under the circumstance of (i) $\Delta = 0, \Omega \gg \Gamma_1 \gg \Gamma_2$; (ii) $\Omega = 2\Delta \gg \Gamma_1 \gg \Gamma_2$; (iii) $\Delta = 0, \Omega \ll \Gamma_1, \Gamma_2$.

Solution

(a) The effective Hamiltonian is

$$H_{\text{eff}} = -\hbar\Delta |e\rangle\langle e| + \left(\frac{1}{2}\hbar\Omega |e\rangle\langle g| + \text{h.c.}\right) - \frac{i\hbar}{2}(C_1^{\dagger}C_1 + C_2^{\dagger}C_2)$$

$$= -\hbar(\Delta + i\Gamma/2) |e\rangle\langle e| + \hbar(\Omega |e\rangle\langle g| + \text{h.c.})/2,$$
(2)

where the quantum jump operators are

$$C_1 = \sqrt{\Gamma_1} |a\rangle\langle e|, \quad C_2 = \sqrt{\Gamma_2} |g\rangle\langle e|,$$
 (3)

and

$$\Gamma = \Gamma_1 + \Gamma_2. \tag{4}$$

(b) The time evolution can be described using the following algorithm.

```
input: Time step \Delta t, maximal time t_0
  1 Initialize an array \{|\psi_s(t)\rangle\}_{t=n\Delta t} of wave functions with t_0/\Delta t elements
  2 for t \in 0 : \Delta t : t_0
               Pick up a uniformly distributed random number x between 0 and 1
              \begin{split} P_{\mathrm{g}} \leftarrow \Delta t \, \langle \psi_{\mathrm{s}}(t) | C_{1}^{\dagger} C_{1} | \psi_{\mathrm{s}}(t) \rangle \\ P_{\mathrm{a}} \leftarrow \Delta t \, \langle \psi_{\mathrm{s}}(t) | C_{2}^{\dagger} C_{2} | \psi_{\mathrm{s}}(t) \rangle \\ / / \text{ jumping to } | \mathrm{g} \rangle \end{split}
              if 0 < x < P_{\rm g}

|\psi_{\rm s}(t + \Delta t)\rangle \leftarrow \text{normalized } C_1 |\psi_{\rm s}(t)\rangle
  6
              // jumping to |a>
              elseif P_{\rm g} < x < P_{\rm g} + P_{\rm a}
 \mid \psi_{\rm s}(t + \Delta t) \rangle \leftarrow \text{normalized } C_2 \mid \psi_{\rm s}(t) \rangle
               // evolution according to the effective Hamiltonian
10
                |\psi_{\rm s}(t+\Delta t)\rangle \leftarrow \text{normalized } |\psi_{\rm s}(t)\rangle + \frac{\Delta t}{i\hbar}H_{\rm eff}|\psi_{\rm s}(t)\rangle
11
               end
12
13 end
```

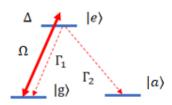

Figure 1: A three-level Λ system

(c) The wave function in this case evolves purely according to $H_{\rm eff}$. Since Schrödinger equation is linear, we can leave the normalization to the end of our calculation. Note that (2) actually does not contain $|a\rangle$ explicitly, nor does the initial state $|g\rangle$. Therefore we can work in the two-level system spanned by $|e\rangle$ and $|g\rangle$. The effective Hamiltonian is

$$H_{\text{eff}} = \hbar \begin{pmatrix} 0 & \Omega^*/2\\ \Omega/2 & -(\Delta + i\Gamma/2) \end{pmatrix}, \tag{5}$$

where we let $|g\rangle$ be the first component and $|e\rangle$ the second. We have the decomposition

$$H_{\text{eff}} = -\frac{\hbar}{2}(\Delta + i\Gamma) + \frac{\hbar}{2}\mathbf{\Omega} \cdot \boldsymbol{\sigma}, \quad \mathbf{\Omega} = (\Omega_{\text{r}}, \Omega_{\text{i}}, \Delta + i\Gamma/2). \tag{6}$$

Note here we cannot "shift the energy zero point" to reshape the Hamiltonian into $\Omega \cdot \sigma$, because the value damping rate has physical meaning. Applying (6) on $|g\rangle$, we have

$$\begin{split} \mathrm{e}^{-\mathrm{i}H_{\mathrm{eff}}t/\hbar}\left|\mathrm{g}\right\rangle &= \mathrm{e}^{\mathrm{i}t(\Delta+\mathrm{i}\Gamma/2)/2}\mathrm{e}^{-\mathrm{i}t\mathbf{\Omega}\cdot\boldsymbol{\sigma}/2}\left|\mathrm{g}\right\rangle \\ &= \mathrm{e}^{-\Gamma t/4}\mathrm{e}^{\mathrm{i}\Delta t/2}\left(\sigma^{0}\cos\frac{\left|\mathbf{\Omega}\right|t}{2} - \frac{\mathrm{i}\mathbf{\Omega}\cdot\boldsymbol{\sigma}}{\left|\mathbf{\Omega}\right|}\sin\frac{\left|\mathbf{\Omega}\right|t}{2}\right)\left|\mathrm{g}\right\rangle \\ &= \mathrm{e}^{-\Gamma t/4}\mathrm{e}^{\mathrm{i}\Delta t/2}\left(\cos\frac{\left|\mathbf{\Omega}\right|t}{2}\left|\mathrm{g}\right\rangle - \left(\frac{\Omega_{\mathrm{r}}}{\left|\mathbf{\Omega}\right|}\left|\mathrm{e}\right\rangle + \frac{\mathrm{i}\Omega_{\mathrm{i}}}{\left|\mathbf{\Omega}\right|}\left|\mathrm{e}\right\rangle + \frac{\Delta+\mathrm{i}\Gamma/2}{\left|\mathbf{\Omega}\right|}\left|\mathrm{g}\right\rangle\right)\mathrm{i}\sin\frac{\left|\mathbf{\Omega}\right|t}{2}\right), \end{split}$$

where

$$|\mathbf{\Omega}| = \sqrt{|\Omega|^2 + \Delta^2 - \Gamma^2/4 + i\Delta\Gamma}.$$
 (7)

Note

Note that here |n| is defined as $\sqrt{n \cdot n}$ instead of $\sqrt{n^* \cdot n}$, because to make

$$e^{i\alpha \boldsymbol{n}\cdot\boldsymbol{\sigma}} = \sigma^0\cos\alpha + i\boldsymbol{n}\cdot\boldsymbol{\sigma}\sin\alpha$$

hold, it is required that

$$(\boldsymbol{n}\cdot\boldsymbol{\sigma})^2=\sigma^0.$$

which is equivalent to $\mathbf{n} \cdot \mathbf{n} = 1$, considering $\{\sigma^i, \sigma^j\} = 0$ when $i \neq j$. What is important here, therefore, is $\mathbf{n} \cdot \mathbf{n}$.

Therefore we have (we have omitted the complex factors, since they will be canceled by normalization anyway)

$$|\psi_{s}(t)\rangle = \frac{1}{C} \left(\cos \frac{|\mathbf{\Omega}| t}{2} - i \frac{\Delta + i\Gamma/2}{|\mathbf{\Omega}|} \sin \frac{|\mathbf{\Omega}| t}{2} \right) |g\rangle - \frac{i\Omega}{|\mathbf{\Omega}|} \sin \frac{|\mathbf{\Omega}| t}{2} |e\rangle, \tag{8}$$

the normalization constant being

$$C = \sqrt{\left|\cos\frac{|\Omega|t}{2} - i\frac{\Delta + i\Gamma/2}{|\Omega|}\sin\frac{|\Omega|t}{2}\right|^2 + \frac{|\Omega|^2}{|\Omega|^2}\sin^2\frac{|\Omega|t}{2}}.$$
 (9)

Since

$$C_1^{\dagger}C_1 = \Gamma_1 |e\rangle\langle e|, \quad C_2^{\dagger}C_2 = \Gamma_2 |e\rangle\langle e|.$$

it is then straightforward that

$$\gamma_1 = \frac{\Gamma_1}{C^2} \frac{\Omega^2}{|\mathbf{\Omega}|^2} \left| \sin \frac{|\mathbf{\Omega}| t}{2} \right|^2, \quad \gamma_2 = \frac{\Gamma_2}{C^2} \frac{\Omega^2}{|\mathbf{\Omega}|^2} \left| \sin \frac{|\mathbf{\Omega}| t}{2} \right|^2. \tag{10}$$

Note that in these equations $|\Omega|^2$ means the norm, i.e. $|\Omega| \cdot |\Omega|^*$.

- (d) Note that γ_1 and γ_2 only differ with a factor, so their plots only differ in scaling.
- (i) In this case $|\Omega| \approx |\Omega|$, so γ_1 and γ_2 oscillate as $A \sin^2 |\Omega| t/2$ until a quantum jump happens, and both of them drop to zero, and then another oscillation starts. See Figure 2a.

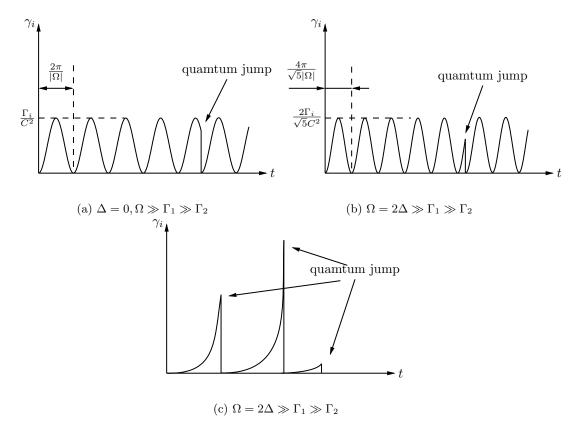

Figure 2: Time evolution of γ_1 and γ_2

(ii) In this case

$$\left| \mathbf{\Omega} \right| \, = \sqrt{\left| \Omega \right|^{\, 2} + \Delta^{2} - \Gamma^{2} / 4 + \mathrm{i} \Delta \Gamma} \approx \sqrt{\left| \Omega \right|^{\, 2} + \frac{1}{4} {\left| \Omega \right|}^{\, 2}} = \frac{\sqrt{5}}{2} {\left| \Omega \right|} \, ,$$

so the case is similar to (i), but the oscillating period is now $4\pi/\sqrt{5}|\Omega|$. See Figure 2b.

(iii) In this case

$$|\Omega| \approx \sqrt{-\Gamma^2/4} = \frac{\mathrm{i}}{2}\Gamma,$$

and we have

$$\gamma_i = \frac{\Gamma_i}{C^2} \frac{\Omega^2}{\Gamma^2/4} \left| \sin \frac{i\Gamma}{2} t \right|^2$$
$$= \frac{\Gamma_i}{C^2} \frac{\Omega^2}{\Gamma^2} (e^{-\Gamma t/4} - e^{\Gamma t/4})^2.$$

Its prefactor is small considering that Ω/Γ is small, but it increases exponentially. Before it grows too large, a quantum jump will happen. See Figure 2c.

Cesium atom Consider a simplified cesium level diagram in Figure 3 (We ignore Zeeman and hyperfine structure). The laser beams at 895 nm, 761 nm and 794 nm induce coupling between the ground state 6 $S_{1/2}-6P_{1/2}$ (with Rabi freq Ω_1), $6P_{1/2}-8$ $S_{1/2}$ (with Rabi freq Ω_2), and 8 $S_{1/2}-6P_{3/2}$ (with Rabi freq Ω_3) respectively. The 1-photon detuning Δ_a , 2– photon detuning Δ_b , and 3-photon detuning Δ_c are sketched as in the diagram. We consider the case where all these detunings are at GHz level or smaller, which are tiny comparing with the optical frequencies of the lasers.

Task 1: With $|g\rangle = |6S_{1/2}\rangle, |a\rangle = |6P_{1/2}\rangle; |b\rangle = |8S_{1/2}\rangle; |c\rangle = |6P_{3/2}\rangle$, invent your own additional notations to write down the time-dependent Hamiltonian for the cesium atom in the laser fields, that explicitly have the optical frequencies of the lasers.

Task 2: Write down a time-independent Hamiltonian.

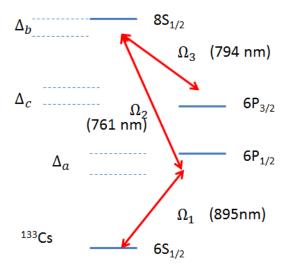

Figure 3: Cesium atom subjected to three laser fields for nearly resonant excitations

Task 3: Consider radiative life time for $6P_{1/2}$, $8S_{1/2}$ and $6P_{3/2}$ are given by $\tau_a = 1/\Gamma_a$, $\tau_b = 1/\Gamma_b$, and $\tau_c = 1/\Gamma_c$. Write down the effective non-Hermitian Hamiltonian $H_{\rm eff}$ that includes an anti-Hermitian part to account for the spontaneous emissions.

Task 4: Consider the internal state of the cesium has a wavefunction $|\psi_S(t)\rangle = c_g|g\rangle + c_a|a\rangle + c_b|b\rangle + c_c|c\rangle$. Consider the weak perturbation limit (ie laser intensities are small enough that atoms are barely excited), write down the differential equations for the coefficients and approximately solve for $|\psi_S(t)\rangle \approx |\tilde{\psi}_S\rangle$ with $H_{\text{eff}}|\tilde{\psi}_S\rangle = 0$.

Task 5: Perturbative calculate the 3-photon scattering rate given by $\gamma_3 = |c_c|^2 \Gamma$, by assuming $|\psi(t)\rangle$ quickly relax to eigenstate of the effective Hamiltonian with $c_g \approx 1$.

Task 6: Consider strong 761 nm and 795 nm laser, calculate the atomic polaraizability $\alpha\left(\Omega_{2},\Omega_{3}\right)$ for the 852 nm laser excitation by evaluating $\langle \mathrm{d} \rangle = \left\langle \widetilde{\Psi_{S}} \left| d_{ag} \right| a \right\rangle \left\langle g \mid \widetilde{\psi_{S}} \right\rangle + \mathrm{c.c.}$, and express it as $\alpha \mathrm{E}_{1} + \mathrm{c.c.}$.

Task 7: Discuss the validity of your method of calculating γ_3 and α (Ω_2, Ω_3) using an ill-defined wavefunction (since its norm cannot be unity) and an effective nonHermitian Hamitonian, instead of using a density matrix and master equations (or the full Monte-Carlo wavefunction method). Your discussion may involve Ω, Δ, Γ and the total time of observation T.

Solution

(1) The time-dependent Hamiltonian is

$$H = H_0 + H_{\text{dipole}},\tag{11}$$

where

$$H_0 = \hbar \omega_{\rm g} |\mathbf{g}\rangle\langle\mathbf{g}| + \hbar \omega_{\rm a} |\mathbf{a}\rangle\langle\mathbf{a}| + \hbar \omega_{\rm b} |\mathbf{b}\rangle\langle\mathbf{b}| + \hbar \omega_{\rm c} |\mathbf{c}\rangle\langle\mathbf{c}|, \tag{12}$$

and

$$H_{\text{dipole}} = -\mathbf{d}_{\text{ag}} \cdot (\mathbf{E}_{1} e^{-i\omega_{1}t} + \mathbf{E}_{1}^{*} e^{i\omega_{1}t}) |a\rangle\langle g| - \mathbf{d}_{\text{ba}} \cdot (\mathbf{E}_{2} e^{-i\omega_{2}t} + \mathbf{E}_{2}^{*} e^{i\omega_{2}t}) |b\rangle\langle a|$$

$$-\mathbf{d}_{\text{bc}} \cdot (\mathbf{E}_{3} e^{-i\omega_{3}t} + \mathbf{E}_{2}^{*} e^{i\omega_{3}t}) |b\rangle\langle c| + \text{h.c.},$$
(13)

where we denote the external electric fields as

$$\boldsymbol{E}_{i} = \boldsymbol{E}_{i0} e^{\mathrm{i}\omega_{i}t} + \boldsymbol{E}_{i0}^{*} e^{-\mathrm{i}\omega_{i}t}, \quad i = 1, 2, 3.$$
(14)

The laser frequencies satisfy

$$\omega_1 + \Delta_a = \omega_a - \omega_g, \quad \omega_2 + \Delta_b - \Delta_a = \omega_b - \omega_a, \quad \omega_3 + \Delta_b + \Delta_c = \omega_b - \omega_c,$$
 (15)

from which we find

$$\omega_1 = \omega_a - \omega_g - \Delta_a, \quad \omega_2 = \omega_b - \omega_a + \Delta_a - \Delta_b, \quad \omega_3 = \omega_b - \omega_c - \Delta_b - \Delta_c.$$
 (16)

(2) We switch to the interaction picture, using H_0 as the free Hamiltonian, and we have

$$H = H_{\text{dipole, int}} = -\mathbf{d}_{\text{ag}} \cdot (\mathbf{E}_{1} e^{-i\omega_{1}t} + \mathbf{E}_{1}^{*} e^{i\omega_{1}t}) |a\rangle\langle g| e^{i(\omega_{a} - \omega_{g})t}$$

$$-\mathbf{d}_{\text{ba}} \cdot (\mathbf{E}_{2} e^{-i\omega_{2}t} + \mathbf{E}_{2}^{*} e^{i\omega_{2}t}) |b\rangle\langle a| e^{i(\omega_{b} - \omega_{a})t}$$

$$-\mathbf{d}_{\text{bc}} \cdot (\mathbf{E}_{3} e^{-i\omega_{3}t} + \mathbf{E}_{3}^{*} e^{i\omega_{3}t}) |b\rangle\langle c| e^{i(\omega_{b} - \omega_{c})t} + \text{h.c.}.$$
(17)

We make the rotating wave approximation, i.e. omitting all terms that vibrate much faster than all detunings, and get

$$H = \frac{1}{2}\hbar\Omega_{1} |a\rangle\langle g| e^{i(\omega_{a} - \omega_{g} - \omega_{1})t} + \frac{1}{2}\hbar\Omega_{2} |b\rangle\langle a| e^{i(\omega_{b} - \omega_{a} - \omega_{2})t} + \frac{1}{2}\hbar\Omega_{3} |b\rangle\langle c| e^{i(\omega_{b} - \omega_{c} - \omega_{3})t} + \text{h.c.},$$
(18)

where we define

$$\frac{1}{2}\hbar\Omega_1 = -\mathbf{d}_{ag} \cdot \mathbf{E}_1, \quad \frac{1}{2}\hbar\Omega_2 = -\mathbf{d}_{ba} \cdot \mathbf{E}_2, \quad \frac{1}{2}\hbar\Omega_3 = -\mathbf{d}_{bc} \cdot \mathbf{E}_3.$$
 (19)

Warning

If we define the electric field as

$$\boldsymbol{E}_{i} = \frac{1}{2} (\boldsymbol{E}_{i0} e^{i\omega_{i}t} + \boldsymbol{E}_{i0}^{*} e^{-i\omega_{i}t}) = |\boldsymbol{E}_{i}| \cos(\omega_{i}t + \varphi_{i}), \quad i = 1, 2, 3,$$
(20)

then there will be no 1/2 factor in the definition of Ω_i 's. However, later we will evaluate $\langle \boldsymbol{d} \rangle$, which has the form of somethinge^{$-i\omega t$} + h.c., and if we insist on (20), an additional and easy-to-forget factor 2 must be added when we evaluate $\alpha = d/E$.

There are three phase factors, and we have four states, so it is possible to use a rotating wave transformation to eliminate them all. By

$$U |a\rangle = e^{-i(\omega_{a} - \omega_{g} - \omega_{1})t} |a\rangle = e^{i\Delta_{a}t} |a\rangle,$$

$$U |b\rangle = e^{-i(\omega_{b} - \omega_{a} - \omega_{2})t} |b\rangle = e^{-i(\Delta_{b} - \Delta_{a})t} |b\rangle,$$

$$U |c\rangle = e^{i(\omega_{a} + \omega_{2} - \omega_{c} - \omega_{3})t} |c\rangle = e^{i(\Delta_{a} + \Delta_{c})t},$$
(21)

we have

$$H \to H' = UHU^{\dagger} - i\hbar U \partial_t U^{\dagger}$$

$$= \frac{1}{2}\hbar\Omega_1 |a\rangle\langle g| + \frac{1}{2}\hbar\Omega_2 |b\rangle\langle a| + \frac{1}{2}\hbar\Omega_3 |b\rangle\langle c| + \text{h.c.} + \hbar\Delta_a |a\rangle\langle a| + \hbar\Delta_b |b\rangle\langle b| - \hbar\Delta_c |c\rangle\langle c|.$$
(22)

This is the time-independent Hamiltonian we want.

(3) The effective Hamiltonian is

$$H_{\text{eff}} = \frac{1}{2}\hbar\Omega_{1} |a\rangle\langle g| + \frac{1}{2}\hbar\Omega_{2} |b\rangle\langle a| + \frac{1}{2}\hbar\Omega_{3} |b\rangle\langle c| + \text{h.c.} + \hbar\underbrace{\left(\Delta_{a} - \frac{i\Gamma_{a}}{2}\right)}_{\tilde{\Delta}_{a}} |a\rangle\langle a|$$

$$+ \hbar\underbrace{\left(\Delta_{b} - \frac{i\Gamma_{b}}{2}\right)}_{\tilde{\Delta}_{b}} |b\rangle\langle b| - \hbar\underbrace{\left(\Delta_{c} + \frac{i\Gamma_{c}}{2}\right)}_{\tilde{\Delta}_{c}} |c\rangle\langle c| .$$
(23)

(4) In the weak perturbation limit, $c_g \approx 1$, and the equation $H_{\text{eff}} |\psi_s\rangle = 0$ is equivalent to

$$\begin{split} &-\frac{1}{2}\hbar\Omega_1^*c_a=0,\\ &\frac{1}{2}\hbar\Omega_1+\hbar\left(\Delta_a-\frac{i\Gamma_a}{2}\right)c_a+\frac{1}{2}\hbar\Omega_2^*c_b=0,\\ &\frac{1}{2}\hbar\Omega_2c_a+\hbar\left(\Delta_b-\frac{i\Gamma_b}{2}\right)c_b+\frac{1}{2}\hbar\Omega_3c_c=0,\\ &\frac{1}{2}\hbar\Omega_3^*-\hbar\left(\Delta_c+\frac{i\Gamma_c}{2}\right)c_c=0. \end{split}$$

The first equation can be throw away because it merely means $c_{\rm a}$ is small. The solutions are therefore

$$c_{a} = -\frac{2\Omega_{1}\tilde{\Delta}_{b}\tilde{\Delta}_{c} + |\Omega_{3}|^{2}\Omega_{1}/2}{|\Omega_{3}|^{2}\tilde{\Delta}_{a} + 4\tilde{\Delta}_{a}\tilde{\Delta}_{b}\tilde{\Delta}_{c} - |\Omega_{2}|^{2}\tilde{\Delta}_{c}},$$

$$c_{b} = \frac{\Omega_{1}\Omega_{2}\tilde{\Delta}_{c}}{|\Omega_{3}|^{2}\tilde{\Delta}_{a} + 4\tilde{\Delta}_{a}\tilde{\Delta}_{b}\tilde{\Delta}_{c} - |\Omega_{2}|^{2}\tilde{\Delta}_{c}},$$

$$c_{c} = \frac{\Omega_{1}\Omega_{2}\Omega_{3}^{*}/2}{|\Omega_{3}|^{2}\tilde{\Delta}_{a} + 4\tilde{\Delta}_{a}\tilde{\Delta}_{b}\tilde{\Delta}_{c} - |\Omega_{2}|^{2}\tilde{\Delta}_{c}}.$$
(24)

(5) We have

$$\gamma_{3} = \Gamma_{3} |c_{c}|^{2} = \frac{|\Omega_{1}|^{2} |\Omega_{2}|^{2} |\Omega_{3}|^{2} / 4}{||\Omega_{3}|^{2} \tilde{\Delta}_{a} + 4 \tilde{\Delta}_{a} \tilde{\Delta}_{b} \tilde{\Delta}_{c} - |\Omega_{2}|^{2} \tilde{\Delta}_{c}|^{2}} \Gamma_{3}.$$
(25)

(6) The total unitary transformation from the original picture to the current pictures is partly given by

$$U_{\text{total}} |g\rangle = e^{i\omega_g t} |g\rangle, \quad U_{\text{total}} |a\rangle = e^{-i(\omega_a - \omega_g - \omega_1)t} e^{i\omega_a t} |a\rangle,$$

so in the current picture, we have

$$\boldsymbol{d} = U_{\text{total}} \boldsymbol{d}_{\text{original}} U_{\text{total}}^{-1}$$

and therefore

$$\langle \boldsymbol{d} \rangle = \langle \psi_{s} | a \rangle e^{i(\omega_{1} + \omega_{g})t} \boldsymbol{d}_{ag} e^{-i\omega_{g}t} \langle g | \psi_{s} \rangle + \text{h.c.} = e^{-i\omega_{1}t} \boldsymbol{d}_{ga} \langle \psi_{s} | g \rangle \langle a | \psi_{s} \rangle + \text{h.c.}$$

$$= -e^{-i\omega_{1}t} \boldsymbol{d}_{ga} \frac{-2\boldsymbol{d}_{ag} \cdot \boldsymbol{E}_{1}}{\hbar} \frac{2\tilde{\Delta}_{b}\tilde{\Delta}_{c} + |\Omega_{3}|^{2}/2}{|\Omega_{3}|^{2}\tilde{\Delta}_{a} + 4\tilde{\Delta}_{a}\tilde{\Delta}_{b}\tilde{\Delta}_{c} - |\Omega_{2}|^{2}\tilde{\Delta}_{c}} + \text{h.c.},$$
(26)

so we have

$$\stackrel{\leftrightarrow}{\alpha} = \frac{d_{\rm ga}d_{\rm ag}}{\hbar} \frac{4\tilde{\Delta}_{\rm b}\tilde{\Delta}_{\rm c} + |\Omega_3|^2}{|\Omega_3|^2\tilde{\Delta}_{\rm a} + 4\tilde{\Delta}_{\rm a}\tilde{\Delta}_{\rm b}\tilde{\Delta}_{\rm c} - |\Omega_2|^2\tilde{\Delta}_{\rm c}}.$$
(27)

When the other two laser beams are very, very strong, we have approximately

$$\stackrel{\leftrightarrow}{\alpha} = \frac{d_{\rm ga}d_{\rm ag}}{\hbar} \frac{|\Omega_3|^2}{|\Omega_3|^2 \tilde{\Delta}_{\rm a} - |\Omega_2|^2 \tilde{\Delta}_{\rm c}}.$$
(28)

(7) What we are doing is to assume (a) that quantum jump is highly impossible on the time scale that we are interested, so the main effect of spontaneous radiation is to renormalize parameters in a pure state problem, and (b) that all perturbations, be it from Ω or Γ , are small enough.

The first condition is equivalent to $\gamma T \ll 1$, where T is the time scale we are interested in. The second condition is equivalent to $|c_a|^2 + |c_b|^2 + |c_c|^2 \ll 1$.

EIT-assisted giant Kerr effect The "lambda"-system composed of $|a\rangle, |e\rangle, |b\rangle$ is further coupled to excited state $|c\rangle$, as in Figure 4. We consider the situation of EIT-resonance: $\delta=0$. We further consider atomic state to be initially in $|\psi(t=0)\rangle=|a\rangle$, and weak-excitation limit is satisfied ($|\Omega_1|$ small "enough"). (a) Write down the effective Hamiltonian for this problem for $\delta=0$. (b) Obtain the approximate stochastic wavefunction in its steady state $|\tilde{\psi}_S\rangle=|a\rangle+c_e|e\rangle+c_b|b\rangle+c_c|c\rangle$ such that $H_{\rm eff}|\psi_S\rangle\approx0$. (c) 3c) Approximately evaluate the atomic dipole moment $\langle d\rangle=\langle \psi_S\,|d_{ae}|\,a\rangle\,\langle e\,|\,\psi_S\rangle+c.c.$ oscillating at the E₁ frequency.

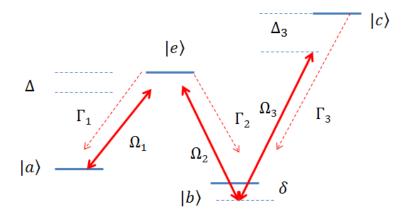

Figure 4: A three-level system coupled to an additional energy level

Solution

(a)
